ABSTRACT

Background
Laparoscopic cholecystectomy has become standard method for treating gallstone. However, different centres have reported different complications and conversion rate. The objective of this study was to evaluate complications and conversion of laparoscopic cholecystectomy into open cholecystectomy in Dhulikhel Hospital, Kathmandu University, Nepal.

Methods
Files of all patients who had laparoscopic cholecystectomy from January 2005 to December 2009 were reviewed. Out of 119 laparoscopic cholecystectomy cases, 102 were included in the study as complete information was lacking in the rest.

Results
Out of 102 cases, 80 were female. Symptomatic cholelithiasis were 76.47%. The mean hospital stay was 2.48 days. Postoperative complications occured in 5.88% patients. Conversion rate to open cholecystectomy was 3.92%.

Conclusions
Laparoscopic cholecystectomy is a reliable and safe surgery. With growing experience in laparoscopic technique, it is possible to bring complications and conversion rate to minimum. However, there will be no significant improvements once learning curve is reached. Rather, the nature of biliary injury may become more severe.

Key Words
cholecystectomy, conversion, gallstone, laparoscopic

INTRODUCTION
At present, laparoscopic cholecystectomy (LC) is the procedure of choice in the surgical treatment of the symptomatic biliary lithiasis. Laparoscopic cholecystectomy has become the standard operative procedure for the treatment of gallbladder diseases and almost replaced open cholecystectomy (OC) in the treatment of gallbladder diseases.¹² The outcome of LC is influenced greatly by training, experience, skill and judgment of the surgeon performing the procedure.¹ This study analyzed the complications and conversion rate of LC.

METHODS
Files of the patients, who had LC done from January 2005 to December 2009, were reviewed. Research was approved by institutional review committee. We collected patients’ demographic data, indications of the surgery, related medical problems, history of previous surgery, preoperative liver function test, reasons for the conversion and the postoperative complications. All the patients presented with cholelithiasis without choledocholithiasis, and with no contraindication for general anaesthesia were included in the study. Out of 119 attempted cases of LC, 102 cases were included in the study as the rest of the
recordswere missing. LC was performed using the closed technique with standard four trocars. Out of 102 cases of LC, four cases were converted to OC. Data were analyzed with Microsoft Excel.

RESULTS

Out of 102 cases, 80 (78.43%) were female and 22 (21.56%) male. The mean age was 42 years (range 16-72 years). One (0.98%) patient had Hypertension and one had Diabetes Mellitus. The indications of laparoscopic cholecystectomy are given in Table 1. The mean hospital stay was 2.48 days (range 2-14 days).

Six patients (5.88%) had postoperative complications. (Table 2)

All the cases of LC were given single prophylactic dose of cefotaxime 1 gram intravenously. In cases of acute calculous cholecystitis, empyema gallbladder and bile spillage, total three doses of cefotaxime 1 gram were given intravenously. Four patients (3.92%) out of 102 were converted to open cholecystectomy. Reasons for conversion were frozen Calot’s triangle in two patients (1.96%), bleeding in one (0.98%) and confusing anatomy at Calot’s triangle in one (0.98%).

DISCUSSION

Laparoscopic cholecystectomy is not easy for the surgeon. Laparoscopic surgery has a learning curve. It needs thorough instruction as well as experience for the improvement of result.

Study done by Keus et al showed morbidity rates of 5.4% following LC. This rate is comparable to our morbidity rate of post LC (5.88%). Eelco J Veen et al had also shown 7% post LC morbidity rates. However, the study has not included biliary injury rate (1%). During the surgical learning curve for LC, there was an initial rise in the reports of bile duct injuries, resulting mainly from the surgeon’s inexperience and misinterpretation of anatomy. However, LC has been still associated with significant bile duct injuries up to 0.5-0.8% and the nature of bile duct injury is more severe. An audit of 1522 LCs performed in Thailand revealed a bile duct injury rate of 0.59%.

In our study, bile duct injury was found in one patient (0.98%) out of 102 cases. In this case, common hepatic duct was clipped instead of cystic duct. It was diagnosed on the 7th postoperative day and managed with Roux-n-y hepatico-jejunostomy.

The biliary leak may be minor, arising from a small accessory bile duct and clinically insignificant. Percutaneous drainage of the bile collected in the subhepatic space is usually sufficient for such cases. In our study, there were 3 (2.94%) cases with bile leak. Subhepatic drainage kept during operation was sufficient to manage biliary leakage. In all cases, there was minimal (<50 ml) bile in the drain. The drain was removed on the 4-5th postoperative day in all cases. In cases where there was doubt about the hemostasis from the raw area of gallbladder fossa, subhepatic drainage was kept during operation. Similarly, in the study done by Muneer Imran et al, two patients (8%) had bile stained drain following laparoscopic cholecystectomy for 2 days. Minor leak was there in both cases and it was stopped spontaneously without requirement of any surgical intervention.

LC has become the first-line surgical treatment of calculous gallbladder disease; however, conversion to OC remains a possibility. Our conversion rate to OC in 102 cases of LC was 3.92%.

Table 3 compares our conversion rate with some major published similar work.

Saeed Hadi et al and Waseen Memon et al claimed that the commonest cause of conversion was frozen Calot’s triangle, which was true in our study also. Frozen Calot’s triangle...
means dense adhesion around Calot’s Triangle

CONCLUSION

Laparoscopic cholecystectomy is a reliable and safe surgery. With growing experience in laparoscopic technique, it is possible to bring complications and conversion rate to minimum. However, there will be no significant improvement once learning curve is reached. Rather, the nature of biliary injury may become more severe.
