#### Abstract

Because of their wide applications in human or animal medicine, the natural products have been the subject of investigation. Aristolochic acids (AAs) (Aristolochiaceae), however toxic, are reported for many medicinal uses. In this work, computational study on the molecular properties of AA II is presented using density functional theory (DFT), B3LYP functional along with Hartree-Fock (HF) theory at $6-311++G(d, p)$ level. A complete vibrational assignment has been done for the observed FT-IR and Raman wavenumbers with the results of quantum chemical calculations. The structureactivity relationship has been interpreted by mapping electrostatic potential surface (MEP). Graphical representation of frontier molecular orbitals with their energy gap has been analyzed theoretically for both the gaseous and solvent environment employing TD-DFT using IEF-PCM model.

## 1. Introduction

Medicinal plants play a fundamental role in the world health, since they are sources of several pharmacologically active compounds such as flavonoids and tannins. Many of these molecular structures are similar to those of our molecules and this is the basis for their physiological action [1]. The use of medicinal plants has been an elected practice throughout human history. It is important to point out that the plants, in addition to their therapeutic use in folk medicine, have contributed to the obtention of many drugs which are still in use, such as morphine, the main anesthetic alkaloid in opium, vincristine etc.

Aristolochic acids (AAs), found in Aristolochia spp, are structurally related nitrophenanthrene carboxylic acids. Drugs derived from Aristolochia plants have been used as medicine in obstetrics and in the treatment of snake bites [2]. The plant extracts have also been used for the therapy of arthritis, gout, rheumatism, and festering wounds [3,4]. However, aristolochic acid is an established human carcinogen $[5,6]$, increase risk of developing urothelial carcinoma [7-11] in the patients with endemic nephropathy and chronic renal failure with some herbal medicines [12].

In this communication, we have presented molecular electrostatic potential surface (MEP), highest occupied molecular orbitals (HOMO)- lowest unoccupied molecular orbital (LUMO), and the vibrational spectra of the molecule aristolochic acid II (AA II) using ab initio HartreeFock (HF) and density functional theory (DFT). With the help of specific scaling procedures, the observed vibrational wavenumbers were analyzed and accurately assigned to different normal modes of the molecule; and using PED's the contributions of the different modes to each wavenumber were determined.

## 2. Methodology

### 2.1 Experimental

Infrared spectra were recorded on a Bruker TENSOR 27 FT-IR spectrometer with a spectral resolution of $4 \mathrm{~cm}^{-1}$ in the region $400-4000 \mathrm{~cm}^{-1}$. KBr pellets of solid samples were prepared from mixtures of KBr and the sample in 200:1 ratio using a hydraulic press. Multi-tasking OPUS software was used for base line corrections.

The FT-Raman spectra were recorded on a Perkin-Elmer 2000R spectrometer as powder sealed in a capillary tube in the region $100-3500 \mathrm{~cm}^{-1}$. The 1064 nm line of an Elforlight Model L04-2000S Nd: YAG laser was used as the exciting source with an output power of about 100 mW at the sample position. All spectra were accumulated for 100 scans with a resolution of $4 \mathrm{~cm}^{-1}$.

### 2.2 Computational

Geometry optimization has been performed as the first task of the computational work. The geometric parameters available from the PubChem data base [13] have been used as the basis for the optimization. The molecular structure, vibrational frequencies and energies of the AA II were computed employing the DFT [14] method using Gaussian 09 program [15] package and Becke's three parameter (local, non-local, Hartree-Fock) hybrid exchange functional with Lee-Yang-Parr correlation functional (B3LYP) [16-18]. The split valence basis set $6-311++\mathrm{G}(\mathrm{d}, \mathrm{p})$, augmented by ' d ' polarization functions on heavy atoms and ' $p$ ' polarization functions on hydrogen atoms as well as diffuse functions for both hydrogen and heavy atoms were used [19,20]. The IR absorption intensities and absolute Raman intensities were calculated in the same level of theory as used for the optimized geometry. The normal mode analysis was performed and the PED was calculated, employing GAR2PED program [21], along the internal coordinates using localized symmetry. For this purpose, a complete set of 90 internal coordinates were defined using Pulay's recommendations [22,23]. The vibrational assignments of the normal modes were done on the basis of the band profile, intensity and PED. Gauss-View program [24] was used for graphical presentation of the calculated Raman and IR spectra. To elucidate the differences of first excitation energies and oscillator strengths in gas and solution, the solvent effects were taken into account by means of integral equation formalism polarizable continuum model (IEF-PCM) [25-27].

## 3. Results and discussion

### 3.1 Geometry optimization

Geometry optimization has been performed as the first task in the ab initio calculations, using the molecular conformation obtained from PubChem data base [13]. The ground state optimized structure (in gas phase) of the molecule is presented in Fig. 1. The optimized parameters have been used for the other calculations. Some of the calculated bond parameters are listed below in the Table 1.

Table 1. Some calculated (DFT) bond parameters of AA II.

| Bond length $(\AA)$ | Bond Angle $\left(^{\circ}\right)$ | Dihedral Angle $\left({ }^{\circ}\right)$ |
| :--- | :--- | :--- |
| $\mathrm{C} 23-\mathrm{O} 4=1.2079$ | $\mathrm{C} 13-\mathrm{C} 23-\mathrm{O} 3=112.74992$ | $\mathrm{C} 17-\mathrm{C} 13-\mathrm{C} 23-\mathrm{O} 3=35.36312$ |
| $\mathrm{O} 4-\mathrm{O} 6=2.87273$ | $\mathrm{C} 12-\mathrm{C} 23-\mathrm{O} 4=124.70005$ | $16-\mathrm{C} 13-\mathrm{C} 23-\mathrm{O} 4=30.81523$ |
| O4-O5 3.17938 | C14-N7-O6 $=116.97323$ | $\mathrm{C} 9-\mathrm{C} 14-\mathrm{N} 7-\mathrm{O} 6=34.44447$ |
| O6-H32 2.27952 | C14-N7-O5 $=117.98883$ | $\mathrm{C} 16-\mathrm{C} 14-\mathrm{N} 7-\mathrm{O} 5=38.83665$ |
| O1-H26 2.13096 | O6-N7-O5 $=124.87079$ | $\mathrm{C} 13-\mathrm{C} 23-\mathrm{O} 3-\mathrm{H} 32=176.71139$ |

Fig. 1. Opitmized structure of AA II.

The equilibrium geometry has been determined by the energy minimization. The energy calculated by DFT (-1121.42720029 Hartree) is lower than the one calculated by HF ( -1114.91828124 Hartree) as it should be. Similarly, the dipole moment calculated by DFT ( 6.6567 Debye) is higher than that calculated by HF (6.4607 Debye).

### 3.2 Molecular electrostatic potential

Molecular electrostatic potential surface is a good tool for assessing the reactive sites towards positively or negatively charged reactants to explain hydrogen bonding and structure-activity of the molecule; however, the molecular charge distribution remains unperturbed through the external test charge [28]. By quantum chemical calculations it is observed that there is a strong correlation between the dipole moment, electro-negativity, and partial charges with electrostatic potential [29]. It provides a visual method to understand the relative polarity of a molecule through mapping total density surface on electrostatic potential energy surface, which depict the size, shape, charge density, and site of chemical reactivity of the molecules.

Fig. 2. (a \& b) MEP (molecular electrostatic potential) (c) ESP (electrostatic potential), and (d) ED (Electron density) mapped on the isodensity surface from -5.5982 e-2 to +5.5982 e-2.

The MEP plots of AA II, shown in the Fig. 2, was based on the calculations performed with B3LYP/6-311++G(d,p) level of theory visualized with Gauss view program 5.0 [30]. In this molecule, regions near the oxygen atoms of methyl group are most negative (red regions) due the concentrated electron density. The regions near the hydrogen atoms of the same group are the most positive regions (blue regions) which correspond to the repulsion of proton by low electron density. The ED (electron density) plots of the investigated molecule show uniform charge distribution. However, yellowish blob from the ESP (electrostatic potential), in the Fig 2(c), reflects that the negative ESP is localized more over the oxygen atoms and the positive ESP is localized on the rest of the molecule. This result is expected, because ESP correlates with electro negativity and partial charges.

### 3.3 Frontier molecular orbitals and electronic absorption

The electronic transition corresponds from HOMO (characterizes of electron giving) to the LUMO (characterizes of electron accepting) orbital. Both the frontier molecular orbitals (FMOs), highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) are the main orbitals taking part in chemical reaction. The electron delocalization between these orbitals is a principal factor in determining the easiness of a chemical reaction and the stereo-selective path, irrespective of intra and intermolecular processes. The energy gap between the HOMO and LUMO molecular orbitals characterizes the chemical reactivity and kinetic stability along with spectroscopic properties [31].

The electronic transitions of high oscillatory strength (f) along with their absorption wavelength ( $\lambda_{\max }$ ) and excitation energies (eV), obtained from the time dependent DFT (TD-DFT) calculation employing $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory $[32,33]$, have been listed in the Table 2.

The negative values of all the FMO energies indicate the stability of the title molecule. The calculation in the gas phase shows that the bands at $389.22,269.69,208.29$ and 206.13 nm originate due to $\mathrm{H} \rightarrow \mathrm{L}, \mathrm{H}-1 \rightarrow \mathrm{~L}+1, \mathrm{H}-4 \rightarrow \mathrm{~L}+2$ and $\mathrm{H}-7 \rightarrow \mathrm{~L}+1$ transitions, respectively. However, the electronic transitions between these FMOs occur with some different values of $\lambda$ and the oscillatory strengths. This discripancy is due to the solvent effect on the molecular orbitals. The HOMO-LUMO plot is shown below in the Fig. 3.

Fig. 3. HOMO-LUMO plot of AA II in the gas phase.

### 3.4 Vibrational wavenumbers

The total number of atoms in AA II molecule is 32 and gives 90 ( $3 \mathrm{~N}-6$; N - the number of atoms) normal modes of vibrations. All the fundamental modes of vibrations are both FT-IR and Raman active. As DFT calculation yields Raman scattering amplitude but not the Raman intensities, so the Raman scattering amplitudes can be predicted for each wavenumber using a relation [34,35];
$\frac{\partial \sigma_{j}}{\partial \Omega}=\left(\frac{2^{4} \pi^{4}}{45}\right)\left(\frac{\left(v_{0}-v_{j}\right)^{4}}{1-\exp \left[\frac{-h c v_{j}}{k T}\right]}\right)\left(\frac{h}{8 \pi^{2} c v_{j}}\right) S_{j}$
where $S_{j}$ and $v_{j}$ are the calculated scattering activities and the predicted wavenumbers, respectively, of the $j^{\text {th }}$ normal mode, $v_{0}$ is the Raman excitation wavenumber and $h, c$ and $k$ are the universal constants.

The calculated Raman and IR intensities were used to convolute each predicted vibrational mode with a Lorentzian line shape (FWHM $=8 \mathrm{~cm}^{-1}$ ) to produce simulated spectra. Since, the DFT and HF vibrational wavenumbers are known to be higher than the experimental wavenumbers due to neglect of anharmonicity effects, they were scaled down by the wavenumber linear scaling procedure (WLS) [ $v_{\text {obs }}=\left(1.0087-0.0000163 v_{\text {calc }}\right) v_{\text {calc }} \mathrm{cm}^{-1}$ ] of Yoshida et al. [36]. Comparison of the wavenumbers, calculated with the HF and DFT method with experimental values, reveals that the DFT method shows very good agreement with experimental observation than the HF due to inclusion of electron correlation, approximate treatment of basis set deficiencies and for the anharmonicity.

The detailed comparison of observed and scaled wavenumbers along with the potential energy distribution is presented in Table 3. The comparison of observed and calculated FT-IR and Raman spectra of AA II molecule is presented in Figs. 4 and 5, respectively. The description of vibrational assignments of the 4 rings and the functional groups has been given below:

### 3.4.1 O-H vibrations

In this molecule, there is one hydroxyl group ( $\mathrm{O}-\mathrm{H}$ ) attached at the ring R2 through carbonyl. The hydroxyl group vibrations are the most sensitive to the environment, so the hydrogen bonded species show pronounced variation in the observables of a spectral band, such as band intensity and shape, frequency position of band maxima. The free hydroxyl group absorbs strongly in the region 3600$3550 \mathrm{~cm}^{-1}$, whereas the existence of hydrogen bond can
lower the O-H stretching wavenumber to the $3550-3200 \mathrm{~cm}^{-1}$ region with an increase in IR intensity and breadth [37]. In our study, the O-H stretching is calculated at $3566 / 3875 \mathrm{~cm}^{-1}$ in scaled DFT/HF and match with very weak band at $3477 \mathrm{~cm}^{-1}$ in the IR spectrum, which indicates the group involvement in intermolecular hydrogen bonding. The O-H deformation is calculated at 1164/1245 $\mathrm{cm}^{-1}$ in the DFT/HF and assigned to the observed peaks at $1149 / 1148 \mathrm{~cm}^{-1}$ in the IR/Raman spectra.

### 3.4.2 $\mathbf{C = O}$ vibrations

Most of the characteristic features of the carboxylic group are observed usually $1750-1600 \mathrm{~cm}^{-1}$ region [38]. C=O bonds being highly polar show intense peak in the IR and weak peak the Raman spectra. The $\mathrm{C}=\mathrm{O}$ stretching vibration is calculated at $1749 \mathrm{~cm}^{-1}$, which match with the observed strong peak at $1687 \mathrm{~cm}^{-1}$ in the IR and weak peak at $1740 \mathrm{~cm}^{-1}$ in the Raman spectra, respectively. The wagging, deformation and rocking of $\mathrm{C}=\mathrm{O}$ are calculated at $800 / 889,665 / 721$ and $431 / 464 \mathrm{~cm}^{-1}$ in the DFT/HF showing good agreements with the observed wavenumbers at 791/797, 650/672 and $420 / 430 \mathrm{~cm}^{-1}$ in the IR/Raman spectra.

Table 3. Observed and calculated FT-IR and Raman wavenumbers $\left(\mathrm{cm}^{-1}\right)$ of AA II.

| Un- | Scaled DFT | Observed |  |  | PED \% |
| :---: | :---: | :---: | :---: | :---: | :---: |

Proposed assignments and potential energy distribution (PED) for vibrational normal modes.
Types of vibration: $v$, stretching; $\delta$, deformation (bending), scissoring; oop, out-of-plane bending; $\omega$, wagging; $\gamma$, twisting; $\rho$, rocking; $\tau$, torsion.
${ }^{\text {a }}$ Potential energy distribution (contribution $\geq 5$ ).

### 3.4.3 $\mathrm{C}-\mathrm{NO}_{2}$ vibrations

There is one nitro $\left(\mathrm{NO}_{2}\right)$ group connected with the ring R 3 as a functional group in this molecule. Generally, the asymmetric $\mathrm{NO}_{2}$ stretching modes are expected in the interval $1600-1500 \mathrm{~cm}^{-1}$ and symmetric stretching modes in the interval $1400-1300 \mathrm{~cm}^{-1}$ in the IR absorption bands [39]. In this study, the asymmetric $\mathrm{N}=\mathrm{O}$ vibration is calculated at $1562 / 1734 \mathrm{~cm}^{-1}$ in the $\mathrm{DFT} / \mathrm{HF}$, which matches well with a weak band at $1539 \mathrm{~cm}^{-1}$ in the IR and the medium intensity band at $1534 \mathrm{~cm}^{-1}$ in the Raman spectrum.
$\mathrm{cm}^{-1}$ in the Raman spectrum. The symmetric $\mathrm{N}=\mathrm{O}$ vibration is calculated at $1353 / 1473 \mathrm{~cm}^{-1}$ in the DFT/HF, which is observed with the weak intensity at $1348 \mathrm{~cm}^{-1}$ in the IR spectrum and the strong peak at $1348 \mathrm{~cm}^{-1}$ in the Raman spectrum. This mode is mixed with $\mathrm{NO}_{2}$ deformation and $\mathrm{C}-\mathrm{N}$ stretching vibration of the ring. The deformation (or scissoring) of $\mathrm{NO}_{2}$ vibration is calculated at $842 / 915 \mathrm{~cm}^{-1}$ in the DFT/HF and observed at $841 / 839 \mathrm{~cm}^{-1}$ in the IR/Raman spectra. The $\mathrm{NO}_{2}$ wagging vibration is calculated at $784 / 860$ in DFT/HF, which is observed at $777 \mathrm{~cm}^{-1}$ in the IR spectrum and $778 \mathrm{~cm}^{-1}$ in the Raman spectrum. The mixed rocking mode vibration of $\mathrm{NO}_{2}$ is calculated at $536 / 580 \mathrm{~cm}^{-1}$ in DFT/HF.

Fig. 4. Observed and calculated FT-IR spectra between the ranges $400-3600 \mathrm{~cm}^{-1}$.

### 3.4.4 Ring R1 vibrations

There is one $\mathrm{CH}_{2}$ moiety in this five membered planer ring. Basically, one can expect six fundamental modes associated with each $\mathrm{CH}_{2}$ group vibrations namely: symmetric, asymmetric stretch, deformation and rocking modes which belong to polarized in-plane vibrations. In addition to that, $\mathrm{CH}_{2}$ wagging and twisting modes would be expected to be depolarized out-of-plane symmetry species. The asymmetric $\mathrm{CH}_{2}$ stretching vibrations are generally observed in the range $3000-2900 \mathrm{~cm}^{-1}$, while the symmetric stretch appears in the region $2900-2800 \mathrm{~cm}^{-1}$ [40,41]. In this study, the pure $\mathrm{CH}_{2}$ asymmetric stretching vibration is calculated at $2998 / 3160 \mathrm{~cm}^{-1}$ in the DFT/HF, which is observed at $2999 \mathrm{~cm}^{-1}$ in the IR spectrum and $2995 \mathrm{~cm}^{-1}$ in the Raman spectrum. Symmetric stretching vibrarion of this group is calculated at $2830 / 3061 \mathrm{~cm}^{-1}$ in the DFT/HF and assigned at $2852 \mathrm{~cm}^{-1}$ in the IR and $2880 \mathrm{~cm}^{-1}$ in the Raman spectra, respectively. The $\mathrm{CH}_{2}$ deformation calculated at $1514 / 1648 \mathrm{~cm}^{-1}$ in the DFT/HF is observed with good agreements with strong band at $1523 \mathrm{~cm}^{-1}$ in the IR and with weak band at $1508 \mathrm{~cm}^{-1}$ in the Raman spectra, respectively. The mixed $\mathrm{CH}_{2}$ wagging vibration is calculated at $1415 / 1569 \mathrm{~cm}^{-1}$ in the DFT/HF, which is assigned at $1417 \mathrm{~cm}^{-1}$ in the IR spectrum and at $1406 \mathrm{~cm}^{-1}$ in the Raman spectrum. The pure $\mathrm{CH}_{2}$ rocking mode is calculated at $1134 / 1223 \mathrm{~cm}^{-1}$ in the DFT/HF. This mode is observed at $1126 \mathrm{~cm}^{-1}$ in the IR and at $1115 \mathrm{~cm}^{-1}$ in the Raman spectra, respectively. The twisting vibration of $\mathrm{CH}_{2}$ is calculated at $1206 / 1302 \mathrm{~cm}^{-1}$ in the DFT/HF.

### 3.4.5 Ring R2 vibrations

An aromatic six membered ring R2 lying between R1 and R3 have a methine (CH) and a carboxyl $(\mathrm{COOH})$ moiety as functional groups. The characteristic region for the identification of C-H stretching in the heteroaromatic structures is $3100-3000 \mathrm{~cm}^{-1}[42,43]$. In this study, the C-H stretching vibration is calculated at $3087 / 3233 \mathrm{~cm}^{-1}$ in the DFT/HF as a pure mode. The observed IR/Raman peaks are at $3038 / 3083 \mathrm{~cm}^{-1}$. The mixed in-plane deformation is calculated at 1189 in DFT and at $1282 \mathrm{~cm}^{-1}$ in HF, respectively. The observed wavenumbers of this mode are $1171 \mathrm{~cm}^{-1}$ in the IR spectrum and at $1173 \mathrm{~cm}^{-1}$ in the Raman spectrum. The C-H out-of-plane deformation is calculated at $899 / 997 \mathrm{~cm}^{-1}$ in the DFT/HF, which is observed at the peaks $901 \mathrm{~cm}^{-1}$ in the IR and at $897 \mathrm{~cm}^{-1}$ in the Raman spectra, respectively.

Fig. 5. Observed and calculated FT-Raman spectra between the range $\mathbf{0 - 3 7 0 0} \mathrm{cm}^{-1}$.

### 3.4.6 Ring R3 vibrations

The six membered ring R3 has a CH and one $\mathrm{NO}_{2}$ moiety. The C-H stretching vibration is calculated at $3065 / 3223 \mathrm{~cm}^{-1}$ in the DFT/HF and observed at $3072 \mathrm{~cm}^{-1}$ in the Raman spectrum. The C-H inplane deformation is calculated at $1217 / 1322 \mathrm{~cm}^{-1}$ in DFT/HF and observed at the very weak band in Raman spectrum. The out-of-plane deformation is calculated at $927 / 1043 \mathrm{~cm}^{-1}$ in the DFT/HF, which is observed in the bands at $920 \mathrm{~cm}^{-1}$ in the IR and at $928 \mathrm{~cm}^{-1}$ in the Raman spectrum, respectively. The mixed C-C ring stretching vibrations are calculated below $772 / 856 \mathrm{~cm}^{-1}$ in the DFT/HF calculations. The highly mixed C-N stretching vibrations are calculated below $1380 \mathrm{~cm}^{-1}$ in DFT with low contributions. The DFT calculation yields C-N out-of plane deformations below $950 \mathrm{~cm}^{-1}$ as mixed modes and with low contributions. Similarly, the C-N and in-plane deformations are calculated below $500 \mathrm{~cm}^{-1}$.

### 3.4.7 Ring R4 vibrations

Ring R4 is also a phenyl ring having four methine moieties and connected with the other ring R3 as shown in the Fig. 1. The C-H stretching vibrations are calculated as the pure modes in the ranges $3106-3032$ in the DFT and $3269-3175 \mathrm{~cm}^{-1}$ in the HF, respectively. The mixed C-H in-plane deformations are calculated at $1504,1528,1271,1182$ and $1148 \mathrm{~cm}^{-1}$ in the DFT, which have good agreements with the observed IR and Raman bands. Similarly, these wavenumbers are calculated at $1630,1603,1344,1266$ and $1264 \mathrm{~cm}^{-1}$ in the HF method. The C-H out-of-plane deformations are calculated below $1000 \mathrm{~cm}^{-1}$ in the DFT. These mixed modes of vibration are calculated below 1110 $\mathrm{cm}^{-1}$ in the HF .
In the DFT, the C-C ring stretching vibrations are calculated at 1618 and $1543 \mathrm{~cm}^{-1}$, which match with the strong peak at $1626,1525 \mathrm{~cm}^{-1}$ in the IR spectrum and with the weak peaks at $1609,1541 \mathrm{~cm}^{-1}$ in the Raman spectrum. The trigonal deformation, puckering, asymmetric deformation and asymmetric torsion of this ring are calculated at $919,772,622$ and $450 \mathrm{~cm}^{-1}$ in the DFT method.

## 4 Conclusion

In the present study, the frequency assignments of the normal modes of AA II using the spectroscopic intuition as well as the quantum chemical calculations were performed. The comparison of the results of experimental and theoretical study has given a full description of the geometry, vibrational wavenumbers and electronic properties of this molecule. The scaled wavenumbers obtained using DFT/HF methods for AA II, showed good correlation with the observed Raman and FT-IR spectra. Any discrepancies noted between the observed and the calculated wavenumbers was observed due to the fact that the calculations have been actually performed on single (or isolated) molecule in the gaseous state. By mapping molecular electrostatic potential surface (MEP) on the electron density isosurface helps in assessing information regarding the size, shape, charge density distribution and sites of chemical reactivity of the title molecule. Our studies have shown that the DFT calculations are qualitative tools for assigning overall understanding of the electronic, structural and vibrational properties of the natural products.
