ABSTRACT

Soil test-based fertility management is important for sustainable soil management. This study was carried out to determine the soil fertility status of the Agriculture Research Station, Belachapi, Dhanusha, Nepal. Using soil sampling auger 25 soil samples were collected randomly from a depth of 0-20 cm. Soil sampling points were identified using GPS device. Following standard methods adopted by Soil Science Division laboratory, Khumaltar, the collected soil samples were analyzed to find out their texture, pH, N, P₂O₅, K₂O, Ca, Mg, S, B, Fe, Zn, Cu, Mn and organic matter status. The soil fertility status maps were made using Arc-GIS 10.1 software. The observed data revealed that soil was grayish brown in colour and sub-angular blocky in structure. The sand, silt and clay content were 36.03±3.66%, 50.32±2.52% and 25.42±2.25%, respectively and categorized as eight different classes of texture. The soil was acidic in pH (5.61±0.14). The available sulphur (0.73±0.09 ppm) status was very low, whereas organic matter (1.34±0.07%), available boron (0.56±0.10 ppm), available zinc (0.54±0.22 ppm) and available copper (0.30±0.01 ppm) were low in status. The extractable potassium (95.52±13.37 ppm) and extractable calcium (1264.8±92.80ppm) exhibited medium in status. In addition, available phosphorus (33.25±6.97 ppm), available magnesium (223.20±23.65 ppm) and available manganese (20.50±2.43 ppm) were high in status. Furthermore, available iron (55.80±8.89 ppm) status was very high. To improve the potentiality of crops (maize, rice, wheat etc.) for studied area, future research strategy should be made based on its soil fertility status.

Keywords: Nutrient management, research efficacy, soil fertility maps; and soil testing

INTRODUCTION

The sustainability of any system has become major concern now days. The evaluation of soil fertility is perhaps the most basic decision making tool in order to impose appropriate nutrient management strategies (Brady & Weil, 2004). There are various techniques for soil fertility evaluation, among them soil testing is the most widely used in the world (Havlin et al., 2010). Soil testing assess the current fertility status and provides information regarding nutrient availability in soils which forms the basis for the fertilizer recommendations for maximizing crop yields and to maintain the adequate fertility in soils for longer period. The texture, structure, colour etc. are important soil physical parameters. Similarly, soil reaction (pH), organic matter, macro and micronutrients etc. are also important soil chemical parameters. The physical and chemical tests provide information about the capacity of soil to supply mineral nutrients (Ganorkar & Chinchmalatpure, 2013). Spatial variation across a field become great challenge for assesses soil fertility of an area. Describing the spatial variability of soil fertility across a field has been difficult until new technologies such as Global Positioning Systems (GPS) and Geographic Information Systems (GIS) were introduced. GIS is a powerful set of tools for collecting, storing, retrieving, transforming and displaying spatial data (Burrough & McDonnell, 1998). Nepal Agricultural Research Council (NARC) was established to strengthen agriculture sector in the country through agriculture research. Agriculture Research Station, Belachapi, Dhanusha is an important wing among the research farms of NARC, in order to generate appropriate agriculture production technologies for central terai of Nepal. The research of different field crops (rice, wheat, maize, pulses etc.) and vegetables are being carried out from longer period of time in the farm. Studies related to the soil fertility status of Agriculture Research Station, Belachapi, Dhanusha are scant. Therefore, it is important to investigate the soil fertility status and it may provide valuable information relating crop research. Considering these facts, the present study was initiated with the objective to assess the soil fertility status of Agriculture Research Station, Belachapi, Dhanusha, Nepal.

MATERIALS AND METHODS

Study area

The study was carried out at Agriculture Research Station, Belachapi, Dhanusha, Nepal (Figure 1). The research farm is situated at the latitude 26° 52'22.7"N and longitude 85°56'54.5"E as well altitude 101masl.

Soil sampling

The surface soil samples (0-20 cm depth) were collected from Agriculture Research Station, Belachapi during January 2015. Altogether soil samples were collected from the research farm by using soil sampling auger (Figure 2). The exact locations of the samples were recorded using a handheld GPS receiver. The random method based on the variability of the land was used to collect soil samples.

Laboratory analysis

The collected soil samples were analyzed at Soil Science Division laboratory, Khumaltar. The different soil parameters tested as well as methods adopted to analyze is shown on the Table 1.

Statistical analysis

Descriptive statistics (mean, range, standard deviation, standard error, coefficient of variation) of soil parameters were computed using the Minitab 17 package. Rating (very low, low, medium, high and very high) of determined values were based on Soil Science Division, Khumaltar. The coefficient of variation was ranked according to the procedure of (Aweto, 1982) where, $CV < 25\%$ = low variation, $CV > 25 \leq 50\%$ = moderate variation, $CV > 50\%$ = high variation. Arc Map 10.1 with geostatistical analyst extension of Arc GIS software was used to prepare soil fertility maps while interpolation method employed was ordinary kriging with stable semi-variogram. Similarly, the nutrient index was also determined by the formula given by Ramamoorthy and Bajaj (1969).

$$\text{Nutrient index (N.I.)} = (N_L \times 1 + N_M \times 2 + N_H \times 3) / N_T$$

Where, N_L , N_M and N_H indicates number of samples falling in low, medium and high classes of nutrient status, respectively and N_T means total number of samples analyzed for a given area. Similarly, interpretation was done as value given by Ramamoorthy shown on the Table 2.

S.N.	Nutrient Index	Value
1.	High	>2.33
2.	Low	<1.67
3.	Medium	1.67-2.33

RESULTS AND DISCUSSION

In the study area its soil fertility status with respect to texture, colour, structure, pH, organic matter, primary nutrients, secondary nutrients and micronutrients such as B, Fe, Zn, Cu, and Mn, was assessed and the results obtained are presented and discussed in the following headings.

Soil texture

Soil texture affects the soil sustainability. The sand, silt and clay are the three components of soil texture. It affects absorption of nutrients, microbial activities, the infiltration and retention of water, soil aeration, tillage and irrigation practices (Gupta, 2004). The % sand of soil samples were ranged from 8.2 to 67.6% with the mean value of 36.03% and that of % silt were 12.8 to 68.8% with a mean of 50.32% while the range of % clay were 3.6 to 39.8% with a mean of 25.42% (Table 3). The coefficients of variation between the soil samples were 75.53%, 25.04% and 44.3% for sand, silt and clay contents, respectively.

Table 3. Soil separates status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Descriptive Statistics	Soil separates (%)		
	Sand	Silt	Clay
Mean	36.03	50.32	25.42
Standard Deviation	18.32	12.60	11.26
Standard Error	3.66	2.52	2.25
Minimum	8.2	12.8	3.6
Maximum	67.6	68.8	39.8
CV%	75.53	25.04	44.3

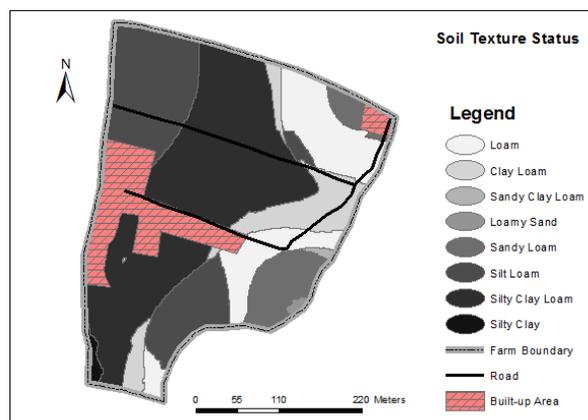

Figure 3. Soil texture status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Soil colour

Soil color reflects on the transformation and translocation occurred in the soil due to chemical, biological and physical attributes (Ponnamperuma & Deturck, 1993). It shows water drainage, aeration and organic matter content in soil. In the majority of the study area, grayish brown (10YR 6/1) colour was observed.

Soil structure

Soil structure refers to the pattern of spatial arrangement of soil particles in a soil mass (Brady & Weil, 2004). In the majority of the area, sub angular blocky structure was observed.

Soil pH

Soil pH is important chemical parameter of soil that affects nutrient availability (Brady and Weil, 2004). The pH of soil was varied from 4.58 to 7.33 with a mean value of 5.61 (Table 4). This indicates moderately acidic soil pH (Figure 4). The availability of various nutrients for plants (rice, wheat, maize, vegetables etc.) may be reduced. Therefore, periodically agricultural lime incorporation is imperative for improvement of soil pH. The soil pH showed low variability (12.41%) among the soil samples.

Table 4. Soil fertility status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Descriptive Statistics	Soil Fertility Parameters (ppm)				
	pH	OM	N	P ₂ O ₅	K ₂ O
Mean	5.61	1.34	0.08	33.25	95.52
Standard Deviation	0.70	0.36	0.01	34.86	66.87
Standard Error	0.14	0.073	0.002	6.97	13.37
Minimum	4.58	0.19	0.04	0.78	21.6
Maximum	7.33	1.92	0.09	145.51	369.6
CV%	12.41	27.15	13.56	104.73	70.01

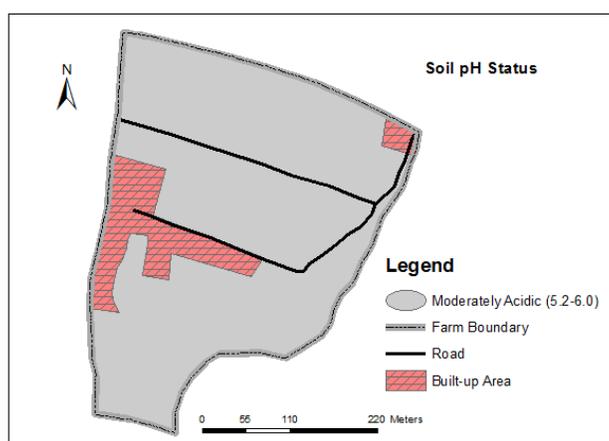

Figure 4. Soil pH status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Organic matter

Organic matter is important source of plant essential nutrients after their decomposition by microorganisms. It supplies plant nutrient, improve the soil structure, water infiltration and retention, feeds soil micro-flora and fauna, and the retention and cycling of applied fertilizer (Johnston, 2007). The organic matter content was varied from 0.19 to 1.92% with a mean value of 1.34% (Table 4). It indicates that the organic matter content was low (Figure 5; Table 7). The

plants don't have tolerance capacity against any kinds of stressed conditions. Therefore, incorporation of organic matter adding materials is imperative for organic matter improvement of soils. Organic matter showed moderate variability (27.15%) among the soil samples.

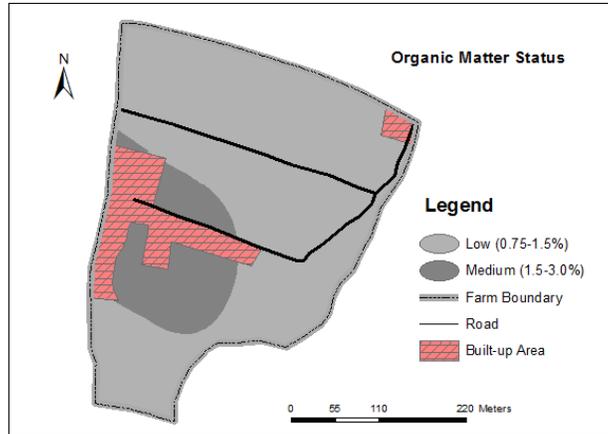

Figure 5. Organic matter status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Total nitrogen

Nitrogen is taken up by plants in greatest quantity next to carbon, oxygen and hydrogen, but in the tropics for crop production it is one of the most deficient elements (Mesfin, 1998). The total nitrogen content was ranged from 0.04 to 0.09% with a mean value of 0.08% (Table 4). This indicates medium content of total nitrogen (Figure 6; Table 7). The nitrogen content is not satisfactory. Therefore, regularly nitrogen adding organic and inorganic materials should be incorporated to make nitrogen balanced in soils. Low variability (13.56%) in total nitrogen was observed among the sampled soils.

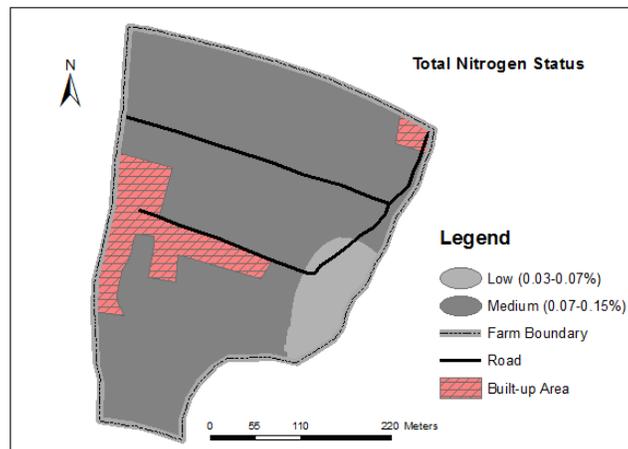

Figure 6. Total nitrogen status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available phosphorus

Phosphorus is the master key to agriculture. The growth of both cultivated and uncultivated plants is limited by availability of P in the soils (Foth and Ellis, 1997). The available phosphorus (P_2O_5) was ranged from 0.78 to 145.51 ppm with a mean value of 33.25 ppm (Table 4). This showed high status of available phosphorus (Figure 7; Table 7). Available phosphorus showed high variability (104.73%) among the tested soil samples.

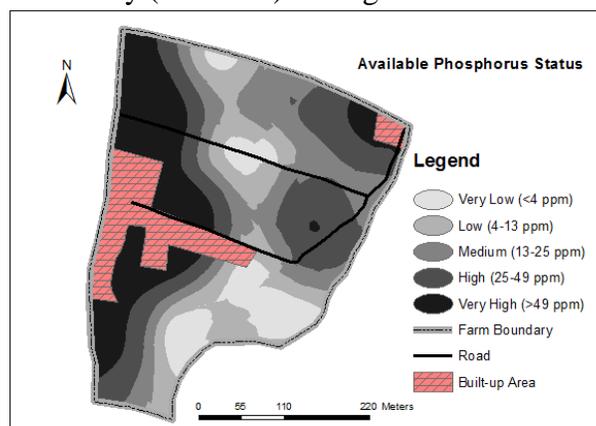

Figure 7. Available phosphorus status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Extractable potassium

Next to N and P, Potassium (K) is the third most important essential element that limit plant productivity. The extractable potassium (K_2O) content was ranged from 21.6 to 369.6 ppm with a mean value of 95.2 ppm. This suggests medium status of extractable potassium (Figure 8; Table 7). High variability (70.01%) in extractable potassium was determined among the soil samples.

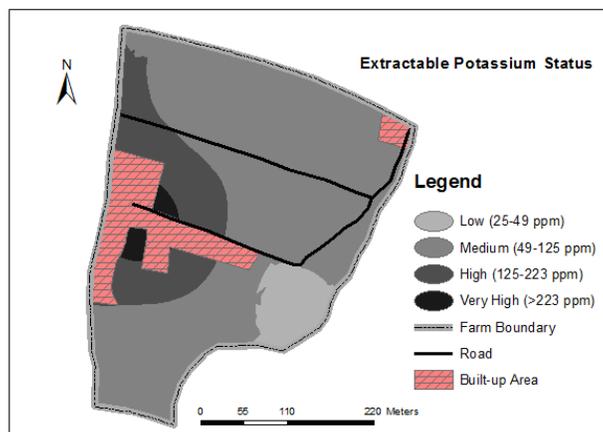

Figure 8. Extractable potassium status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Table 5. Soil fertility status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Descriptive Statistics	Soil Fertility Parameters (ppm)			
	Ca	Mg	S	B
Mean	1264.80	223.20	0.73	0.56
Standard Deviation	463.98	118.24	0.44	0.52
Standard Error	92.80	23.65	0.088	0.10
Minimum	180	12	0.29	0.15
Maximum	2080	432	1.81	2.61
CV%	36.7	53.0	59.7	91.9

Extractable calcium

Calcium is a secondary nutrient important for cell division in plants. The calcium content was ranged from 180 to 2080 ppm with a mean value of 1264.80 ppm (Table 5). In overall, medium status of extractable calcium was observed (Figure 9; Table 7). Moderate variability (36.7%) in extractable calcium was observed among the soil samples.

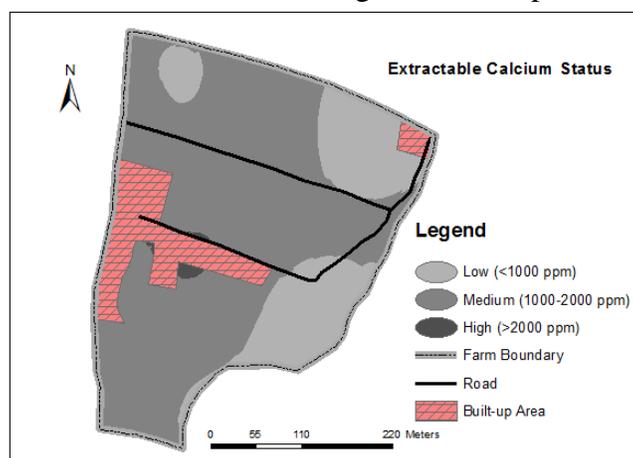

Figure 9. Extractable calcium status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Extractable magnesium

Magnesium is a water soluble cation necessary for chlorophyll pigment in green plants (Mahajan & Billore, 2014). The magnesium content was ranged from 12 to 432 ppm with a mean value of 223.20 ppm (Table 5). This revealed high content of extractable magnesium (Figure 10; Table 7). The variation (53 %) in the extractable magnesium of the observed samples is high.

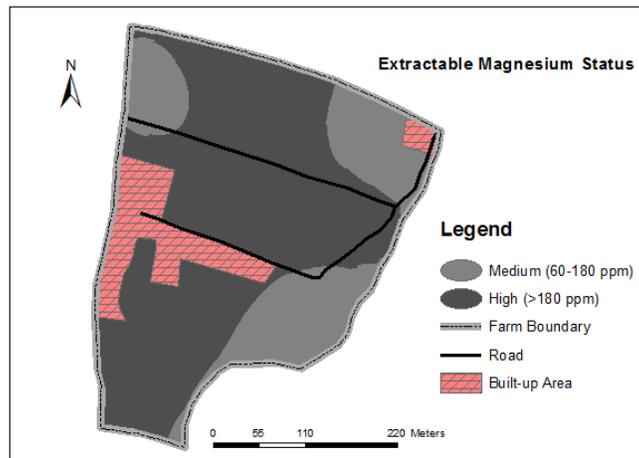

Figure 10. Extractable magnesium status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available sulphur

Sulphur is required for synthesis of S-containing amino acids cystine, methionine and cysteine, and these are essential components of protein that comprise about 90% of the total S in plants (Havlin et al., 2010). The available sulphur was varied from 0.29 to 1.81 ppm with a mean value of 0.73 ppm (Table 5). In overall, available sulphur was very low in status (Figure 11; Table 7). Therefore, regularly sulphur adding organic and inorganic materials should be incorporate to reduce sulphur mining problem in soils. Organic matter improvement is also one option for enhancing availability of available sulphur. Available sulphur showed high variability (59.7%) in the soil samples.

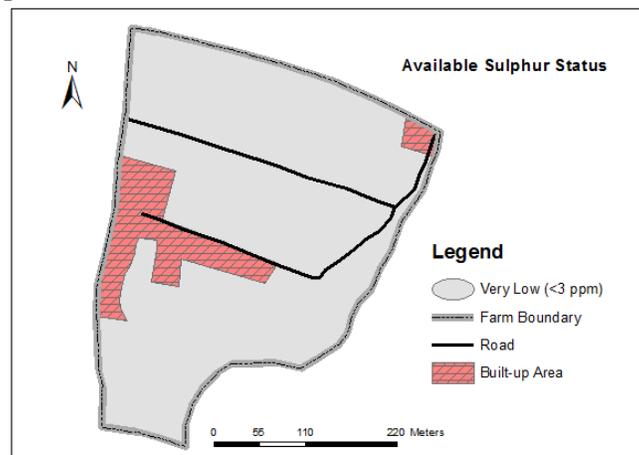

Figure 11. Available sulphur status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available boron

Boron is required by plants for their cell wall structural integrity (Havlin et al., 2010). The available boron content was ranged from 0.15 to 2.61 ppm with a mean value of 0.56 ppm (Table 5). This indicates low content of available boron (Figure 12; Table 7). Therefore, regularly boron adding organic and inorganic materials should be incorporate to maintain boron

adequate in soils. High variability (91.9%) in available boron was observed among the soil samples.

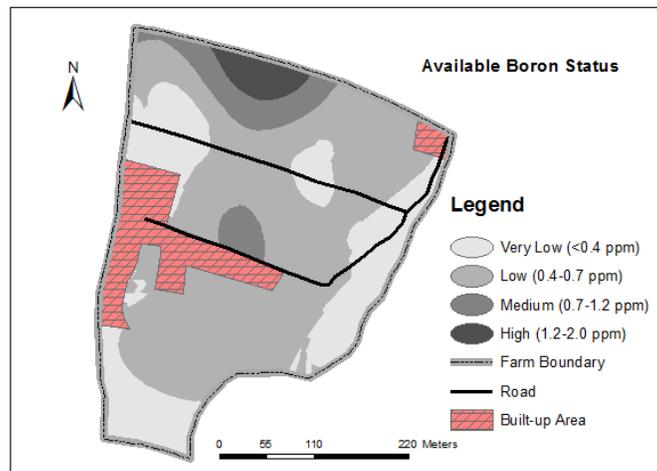

Figure 12. Available boron status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available iron

Iron is an essential micronutrient for almost all living organisms because of it plays critical role in metabolic processes such as DNA synthesis, respiration, and photosynthesis (Rout & Sahoo, 2015). The available iron content was ranged from 5.56 to 160.7 ppm with a mean value of 55.80 ppm (Table 6). In overall, available iron status was high (Figure 13; Table 7). There may have high possibility for stress of iron toxicity as well deficiency of antagonistic elements in plants. Therefore, nutrients like potassium; phosphorus etc. should be applied in adequate amount for reducing iron toxicity stress in plants. Available iron showed high variability (79.7%) among the soil samples.

Table 6. Soil fertility status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Descriptive Statistics	Soil Fertility Parameters			
	Fe	Zn	Cu	Mn
	ppm			
Mean	55.80	0.54	0.30	20.50
Standard Deviation	44.45	1.08	0.06	12.14
Standard Error	8.89	0.22	0.01	2.43
Minimum	5.56	0.08	0.12	5.62
Maximum	160.7	5.58	0.4	47.5
CV%	79.7	199.7	21.4	59.3

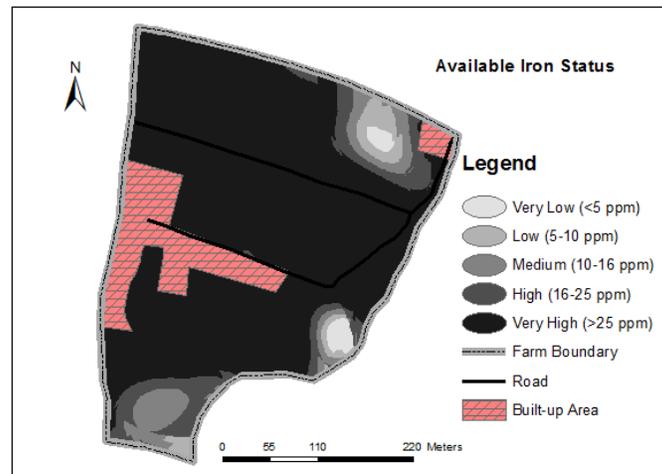

Figure 13. Available iron status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available zinc

Zinc is essential for several biochemical processes in plants, such as cytochrome and nucleotide synthesis, auxin metabolism, chlorophyll production, enzyme activation, and the maintenance of membrane integrity (Havlin et al., 2010). The available zinc content was ranged from 0.08 to 5.58 ppm with a mean value of 0.54 ppm (Table 6). This indicates low status of available zinc (Figure 14; Table 7). There may have high possibility of zinc deficiency symptoms like white bud in maize, khaira disease in rice etc. Therefore, different organic and inorganic sources of zinc should be applied in the field regularly to reduce zinc stress in plants. The available zinc showed high variability (199.7%) among the soil samples.

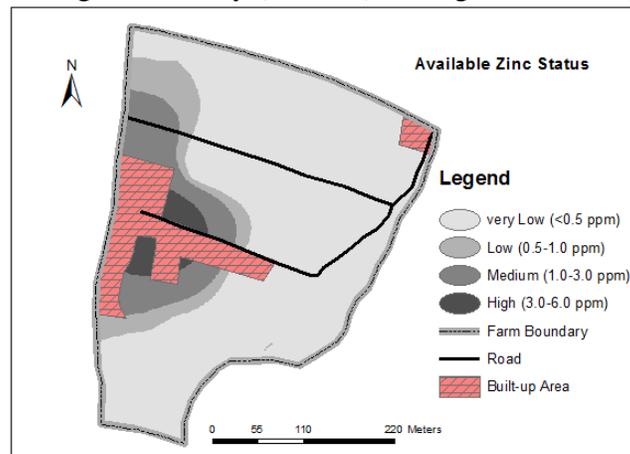

Figure 14. Available zinc status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available copper

Copper is also important micronutrient for plants, and required for lignin synthesis and acts as a constituent of ascorbic acid, oxidase, phenolase and plastocyanin (Havlin et al., 2010). The available copper content was varied from 0.12 to 0.4 ppm with the mean value of 0.30 ppm (Table 6). This indicates low status of available copper (Figure 15; Table 7). Therefore, proper

copper management strategy should be adopted to make copper balanced in soils. Low variability (21.4%) in available copper was recorded among the soil samples.

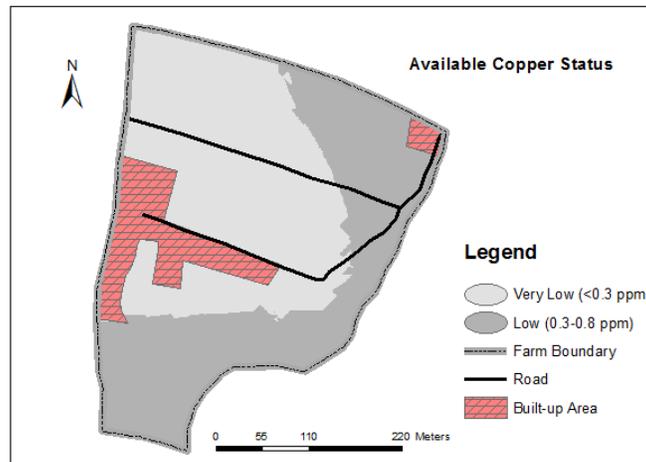

Figure 15. Available copper status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Available manganese

Manganese plays an important role in oxidation and reduction processes in plants (Mousavi et al., 2011). The available manganese content was ranged from 5.62 to 47.5 ppm with the mean value of 20.50 ppm (Table 6). This indicates high status of available manganese (Figure 16; Table 7). The available manganese showed high variability (59.3%) among the studied soil samples.

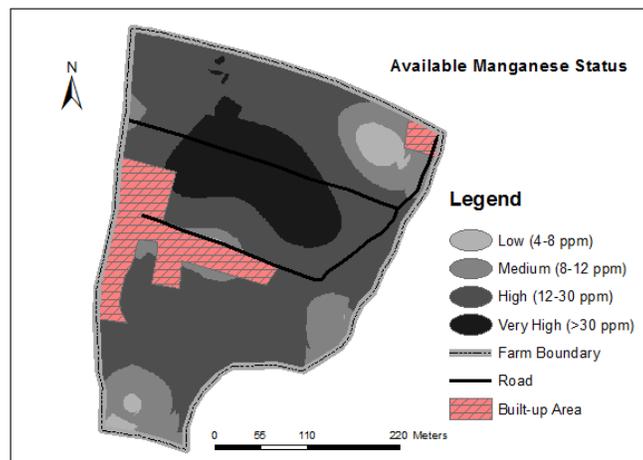

Figure 16. Available manganese status of Agriculture Research Station, Belachapi, Dhanusha, Nepal

Table 7. Nutrient indices of studied parameters of Agriculture Research Station, Belachapi, Dhanusha, Nepal

S.N.	Parameters	% distribution of samples					Nutrient index	Remarks
		Very Low	Low	Medium	High	Very High		
1.	OM	4	64	32	-	-	1.32	Low
2.	N	-	40	60	-	-	1.6	Low
3.	P ₂ O ₅	20	8	20	28	24	2.24	Medium
4.	K ₂ O	4	12	68	12	4	2.0	Medium
5.	Ca	-	32	64	4	-	1.4	Low
6.	Mg	-	8	36	56	-	2.48	High
7.	S	100	-	-	-	-	1.0	Low

9.	Fe	-	12	4	16	68	2.72	High
10.	Zn	84	8	4	4	-	1.12	Low
11.	Cu	36	64	-	-	-	1.0	Low
12.	Mn	-	12	20	40	28	2.56	High

CONCLUSION

Overall, the colour of soil was grayish brown and structure was sub-angular blocky. Soils were acidic in reaction and it is advisable to apply agricultural lime periodically for its amelioration. The sulphur status was very low. The organic matter, boron, zinc and copper status were low. The nitrogen, potassium and calcium status were medium. The phosphorus, magnesium and manganese status were high. The iron was very high in status. The crops (maize, rice, wheat etc.) may suffer from deficiency of low and toxicity of very high plant available nutrients. Thus, proper nutrient management strategy should be adopted especially for these nutrients. Considering the low status of soil organic matter, the practices like manure or compost incorporation, crop residue retention, green manuring etc. can be suggested for its improvement. From this study, it can be concluded that for enhancing efficacy of the agricultural research (maize, rice, wheat etc.) future research strategy should be built based on the soil fertility status of the farm.

ACKNOWLEDGEMENTS

The authors would like to acknowledge Nepal Agricultural Research Council for funding this research. We are very much thankful to Agriculture Research Station, Belachapi, for their cooperation. Similarly, support of the Soil Science Division, Khumaltar for providing laboratory facilities to analyze the soil samples and preparation of soil fertility maps as well as other technical support is highly acclaimed.
